Programming Assignment

Implement the following sorting algorithms and to collect time performance measurements on them.

- 1. Insertion sort
- 2. Heap sort
- 3. Merge sort
- 4. Quick sort.(version 1, version 2, version 3)

version 1: first or last element as a pivot

version 2: random number as a pivot

version 3: median of three partitioning as a pivot.

version 4(optional): your strategy(wisely but efficiently)

The running time of each sorting algorithm must be measured in two ways:

A. Count the number of key comparisons, COMPCOUNT.

To obtain this count, it is suggested that you write a function COMPARE(X,Y), which will perform a comparison between X and Y and increment COMPCOUNT.

Then, wherever you need to perform a key comparison in your algorithms, you simply make a call to this function.

B. Use the actual measured CLOCK time.

The experiment in two parts.

For simplicity, you may use integers. For each case, make sure the same original data is input to all four algorithms

- 1. A small array size, n = 32, to verify correctness Run each algorithm on two sets of data:
 - (1) Sorted, (2) Randomly generated.
- 2. Large array sizes (n=2¹⁰=1024) for randomly generate data to determine time complexity

Tabulate the performance results, listing both the number of comparisons and the measured clock times.
